Performance Evaluation of WebSocket
Protocol for Implementation of Full-Duplex
Web Streams

Oleg Bilovus

Università degli Studi di Salerno

1st Scalability Research Forum

We will talk about WebSockets and compare its performance with TCP Socket. But, before diving into analyzing the performance we need to understand why we needed WebSockets and what they are.

HTTP polling

2024-06-03

A client can send data and ask for data at the same time. But, if client has no data and server has no data, a request and response will still be generated with all the HTTP headers and thus wasting resources. No real-time data because while the client waits, an event could occur and the client will know about it only when the timeout expires.

    end
```

A client can send data and ask for data at the same time. But, if client has no data and server has no data, a request and response will still be generated with all the HTTP headers and thus wasting resources. No real-time data because while the client waits, an event could occur and the client will know about it only when the timeout expires.

HTTP long polling

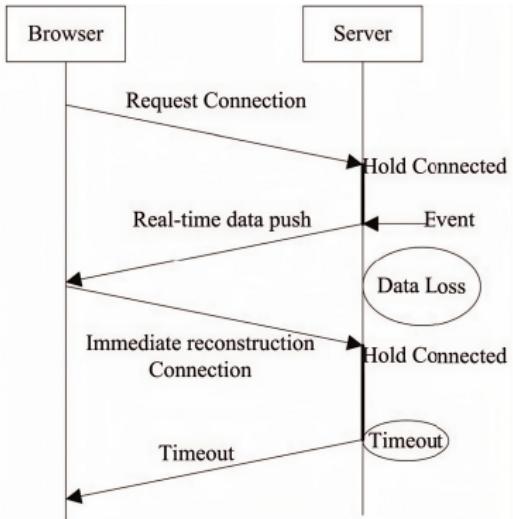

When a client sends a data request, the server will block the request until there is data transfer or timeout before returning.

Can hold the connection up to a certain time, after that a timeout is exceeded and need a new connection. No bidirectional because the client may only send data the first time, but then it will only receive until a timeout and another request is made. In the normal polling we could have bidirectional because the interval was shorter.

HTTP long polling

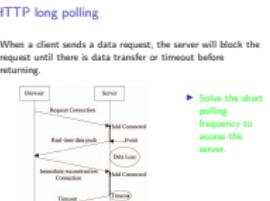

When a client sends a data request, the server will block the request until there is data transfer or timeout before returning.

► Solve the short polling frequency to access the server.

- ▶ It can send multiple events from a single request.
- ▶ But, it increases the burden on the server, causing the server performance degradation, or even collapse.

The diagram illustrates the communication flow between a Browser and a Server via an iframe:

- The Browser initiates a **Request Connection** to the Server.
- The Server responds with a **Hold Connection**.
- The Server performs **Hold Connection** and **Read Frame data push**.
- The Browser sends **Event** to the Server.
- The Server handles the event and may experience **Data Loss**.
- The Server performs **Immediate reconstruction** and **Send Frame**.
- The Browser sends **Event** to the Server.
- The Server handles the event.

Streaming

iframe is a html page inside another. Because the server need to keep the connections alive.

Streaming
Iframes embed a hidden frame in an HTML page, then set it as a long connection request, thus the server can send data to the clients constantly.

- ▶ It can send multiple events from a single request.
- ▶ But, it increases the burden on the server, causing the server performance degradation, or even collapse.
- ▶ No bidirectional communication.

The diagram illustrates the flow of data between a Browser and a Server using an iframe:

- The Browser sends a **Request Connection** to the Server.
- The Server responds with a **Hold Connection**.
- The Server performs a **Real-time data push** to the Browser.
- The Browser sends an **Event** back to the Server.
- This cycle repeats with another **Real-time data push** and an **Event** from the Browser.
- After two such cycles, a **Timeout** occurs on the Server side.
- The Server handles **Data Loss** and initiates **Immediate reconstruction**.
- A new **Connection** is established, and the process resumes with another **Real-time data push** and an **Event** from the Browser.

RFC 6455
Keywords

▶ The WebSocket Protocol enables two-way communication between a client running untrusted code in a controlled environment to a remote host that has opted-in to communications from that code.

opted-in is important because with polling any HTTP server would accept it, but here additional steps are needed. Handshake means client and server have to agree that they can both use the protocol and the server has to prove it. Message framing because we do not want to send every time the headers. TCP means it is reliable, no messages will be lost.

RFC 6455

Keywords

- ▶ The WebSocket Protocol enables **two-way communication** between a client running untrusted code in a controlled environment to a remote host that has opted-in to communications from that code.

TCP means it is reliable, no messages will be lost.

- ▶ The WebSocket Protocol enables **two-way communication** between a **client** running untrusted code in a controlled environment to a **remote host** that has **opted-in** to communications from that code.
- ▶ The protocol consists of an opening **handshake** followed by basic **message framing**, layered over **TCP**.
- ▶ The goal of this technology is to provide a mechanism for browser-based applications that need two-way communication with servers.

WebSocket

- WebSocket protocol
 - Definition
 - RFC 6455

RFC 6455
Keywords

- ▶ The WebSocket Protocol enables **two-way communication** between a **client** running untrusted code in a controlled environment to a **remote host** that has **opted-in** to communications from that code.
- ▶ The protocol consists of an opening **handshake** followed by basic **message framing**, layered over **TCP**.
- ▶ The goal of this technology is to provide a mechanism for browser-based applications that need two-way communication with servers.

opted-in is important because with polling any HTTP server would accept it, but here additional steps are needed. Handshake means client and server have to agree that they can both use the protocol and the server has to prove it. Message framing because we do not want to send every time the headers. TCP means it is reliable, no messages will be lost.

There is the initial handshake, after that, client and server can send and receive data at any moment without further interaction. There is no timeout. If it disconnects, it is because of an error and to establish the connection, the handshake has to be done again.

Handshake

- ▶ For WebSocket-based communication, a **WebSocket session** should be established first.

WebSocket Frame Structure

We will not go into the details because it is out of the scope of this presentation and, as mentioned earlier, the added overhead to the payload data is minimal.

Callback	Description
onopen	invoked when WebSocket session is established, signalizes that the protocol is ready to transfer payload data
onerror	invoked whenever an error occurs
onclose	invoked when one of the peers has terminated the session
onmessage	invoked when an incoming message from another peer has arrived

WebSocket API

The API is defined by its states of readiness, responses to a networking or messaging **event**.

 - ▶ Handshake
 - ▶ Frame header for each frame

- ▶ Both protocols will have the lower level protocols fields overhead such as *Ethernet, IP and TCP header*.
- ▶ For this reason, the analysis consider only the overhead the WebSocket incurs:
 - ▶ Handshake
 - ▶ Frame header for each frame

Handshake overhead

- The overhead is **fixed in length** and typically counts few hundreds of bytes.
- It is **performed only once** per session.

Handshake overhead

- ▶ The overhead is **fixed in length** and typically counts few hundreds of bytes.
- ▶ It is **performed only once** per session.
- ▶ Its **significance decreases** with the increasing number of frames sent over the same session. Thus, the evaluation is focused on long-running sessions.

Results
► When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.

Results

- ▶ When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.
- ▶ With WebSocket, the TCP Payload consists of both data and Frame header.

Results

- ▶ When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.
- ▶ With WebSocket, the TCP Payload consists of both data and Frame header.

Results

- ▶ When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.
- ▶ With WebSocket, the TCP Payload consists of both data and Frame header.
- ▶ This relation can be written as:

$$P_{TCP} = data \quad (1)$$

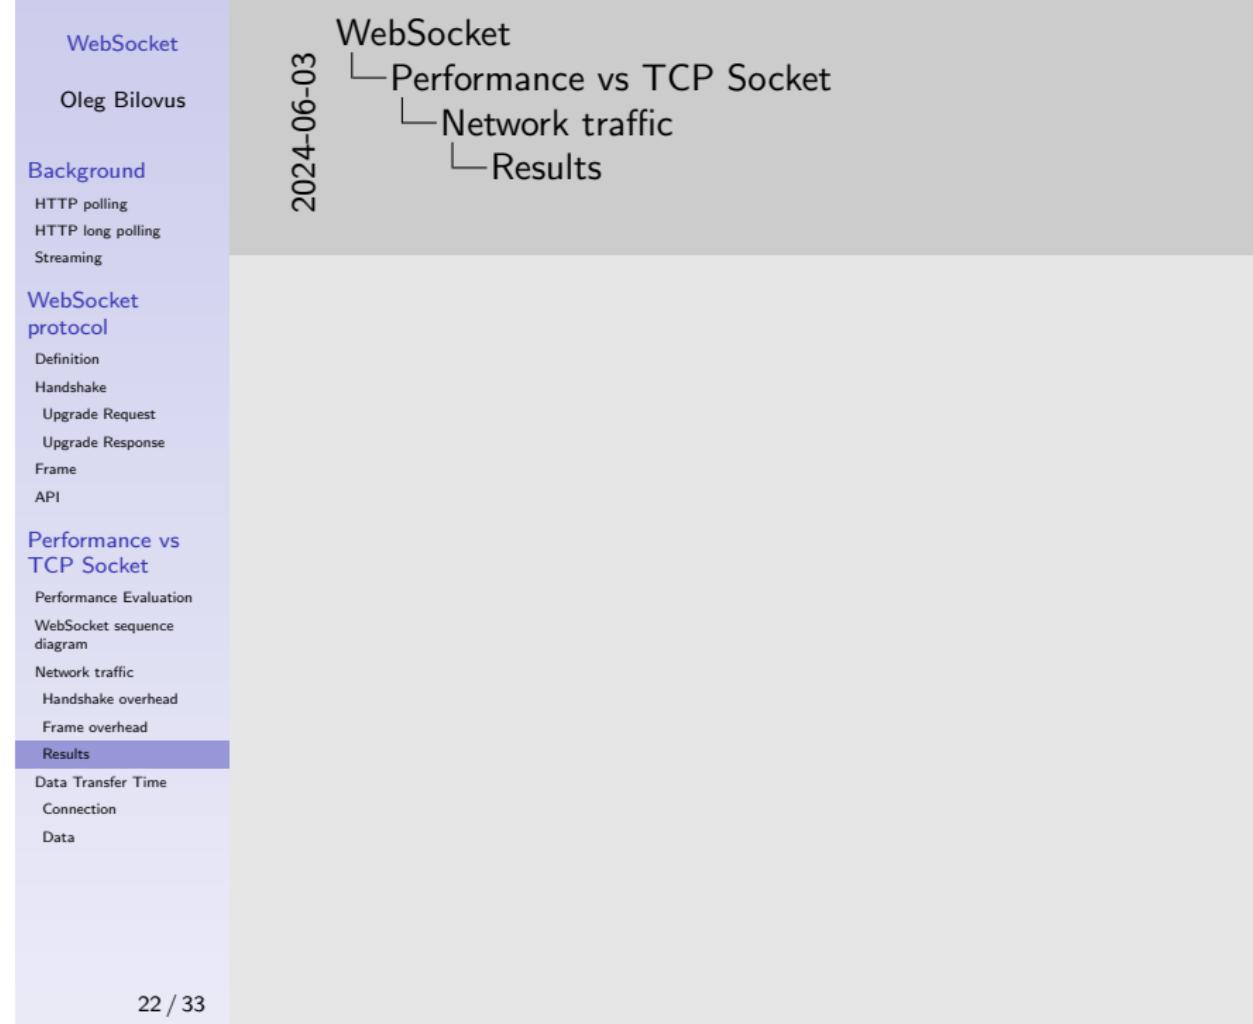

$$P_{WS} = data + H \quad (2)$$

where:

P = payload

$data$ = data to send

H = length of frame's header

Results

- ▶ When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.
- ▶ With WebSocket, the TCP Payload consists of both data and Frame header.
- ▶ This relation can be written as:

$$P_{TCP} = \text{data} \quad (1)$$

$$P_{WS} = \text{data} + H \quad (2)$$

where:

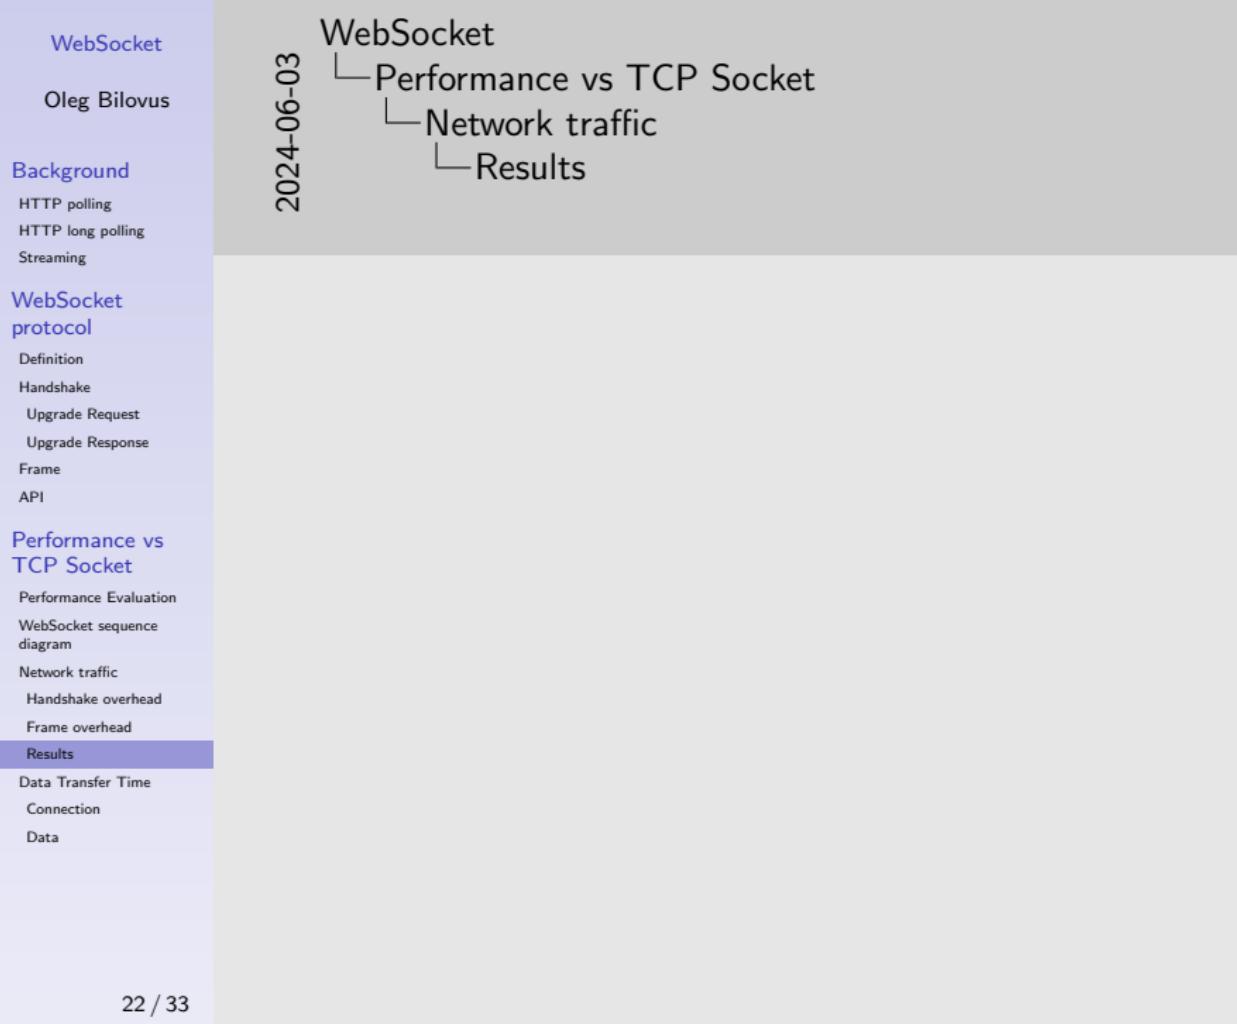

P = payload

data = data to send

H = length of frame's header

- ▶ We can now define the **network traffic overhead O_P** a WebSocket has over a TCP Socket:

$$O_P = \frac{P_{WS} - P_{TCP}}{P_{TCP}} \cdot 100\% \quad (3)$$

Results

- ▶ When the data are transferred with TCP Socket, they are **directly embedded as TCP Payload**.
- ▶ With WebSocket, the TCP Payload consists of both data and Frame header.
